**Laboratory work No. 1**

Student : Hanna Asiadouskaya

Lecturer: dr. Nerijus Ramanauskas

Šiauliai, 2025

## Aim of the laboratory work:

The aim is to practice and understand the basics of MicroPython programming for microcontrollers, working on STM32 Nucleo F756ZG board with solder bridges and learn how to configure several I/Os and power supply pins for compatibility. Understanding pull-up and pull-down resistors.

## Variant No 2.

Button 1			Button 2		
Pin	Pull Up/Down	Action on button press	Pin	Pull Up/Down	Action on button release
A1	Pull Down	Increment variable	A2	Pull Up	Toggle LED1

## Code and Comments:

Importing library to control and read from microcontroller pins and another to work with delays.

Configures the pin "LED1" as an output for an LED. A1 as input and pull down (0) and A2 as input and pull up (1)

Declaration of the state of button presses and variable, to count increment.

```
from machine import Pin
import time
green_LED = Pin("LED1", Pin.OUT)
pin_A1 = Pin("A1", Pin.IN, Pin.PULL_DOWN)
pin_A2 = Pin("A2", Pin.IN, Pin.PULL_UP)
b1_state = True
b2_state = True
iterator = 0
```

Here is while true statement, to keep the code running, so the board can detect presses.

If the button pressed -> increase iterator, print variable and change the state of the pressed button.

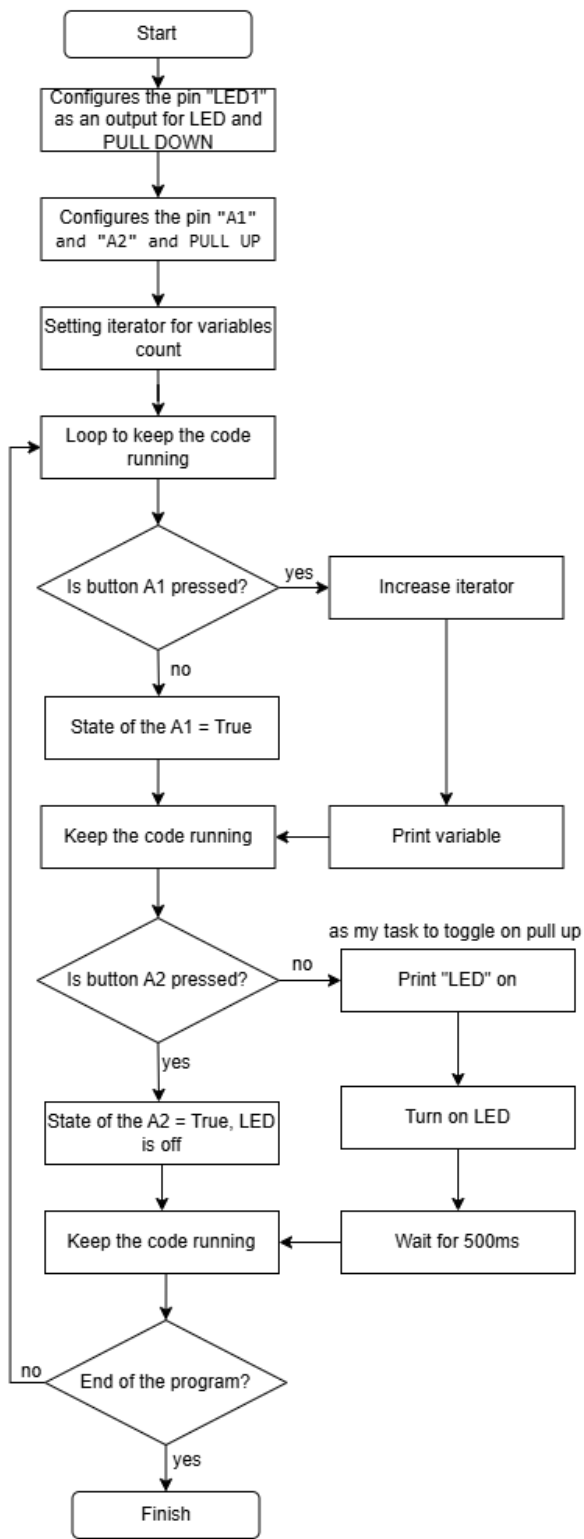

If the button released, the statement keep it's position.

```
while True:
    if pin_A1.value()==1:
        if b1_state:
            iterator += 1
            print(f"Variable value: {iterator}")
            b1_state = False
        else:
            b1_state = True
```

The next if statement change the LED to off, as pressed, as my task was to toggle the LED on pull up, so the default position is equal to 1. If the button released the light is on.

```
if pin_A2.value()==1:
    if b2_state:
        print("LED on")
        green_LED.high()
        time.sleep_ms(500)
        b2_state = False
    else:
        b2_state = True
        green_LED.low()
```

## Algorithm:

## Conclusion:

In this study, we successfully practiced the basics of MicroPython programming on the STM32 Nucleo F756ZG microcontroller, explored hardware configurations, including solder bridges, were focusing on configuring and using digital inputs and outputs and learned how to handle pins, and in general this project provided hands-on experience with microcontroller I/Os.

## Code as a text:

```
from machine import Pin

import time

green_LED = Pin("LED1", Pin.OUT)

pin_A1 = Pin("A1", Pin.IN, Pin.PULL_DOWN)

pin_A2 = Pin("A2", Pin.IN, Pin.PULL_UP)

b1_state = True

b2_state = True

iterator = 0

while True:

    if pin_A1.value() == 1:

        if b1_state:

            iterator += 1

            print(f"Variable value: {iterator}")

            b1_state = False

        else:

            b1_state = True

    if pin_A2.value() == 1:

        if b2_state:

            print("LED on")

            green_LED.high()

            time.sleep_ms(500)

            b2_state = False

        else:

            b2_state = True

            green_LED.low()
```
